TITLE: Shape of the angular distribution of shower particles

PERIODICAL: Zhurnal eksperimental'noy i teoreticheskoy fiziki, v. 43,  
no. 2(8), 1962, 454-458

TEXT: It has been shown (Nuovo Cim. 18, 102, 1960; Phys. Rev. 122, 626, 1961) that in nuclear emulsions the distribution of secondary particles produced by nucleons of  $> 10^{12}$  ev with respect to  $x = \log \tan \theta$  is not normal in spite of the predictions of the hydrodynamic theory of head-on collisions; ( $\theta$  is the angle between the direction of flight of the primary particle and that of emission of the secondary one in the laboratory system). The authors propose new criteria for investigating the angular distribution of secondary shower particles with any  $n_s$  ( $n_s$  = number of particles in the shower). If the distribution of the quantities  $x_i$  is normal, the random functions

Card 1/3

Shape of the angular distribution ...

S/056/62/043/002/015/053  
B102/B104

$$d_1 = \sqrt{\frac{(n_s + 1)(n_s + 3)}{6(n_s - 2)}} g_1,$$

$$d_2 = \sqrt{\frac{(n_s + 1)^2(n_s + 3)(n_s + 5)}{24n_s(n_s - 2)(n_s - 3)}} \left[ g_2 + \frac{6}{n_s + 1} \right], \quad (2)$$

with

$$g_1 = m_3 / \sqrt{m_2^3}, \quad g_2 = m_4 / m_2^2 - 3;$$

$$m_k = \frac{1}{n_s} \sum_{l=1}^{n_s} (x_l - \bar{x})^k, \quad \bar{x} = \frac{1}{n_s} \sum_{l=1}^{n_s} x_l. \quad (1)$$

can be formulated, whose expectation values are zero and the dispersion is unity, irrespective of the distribution parameters of  $x$  and of the number

of shower particles. The mean value  $\bar{d}_k = \frac{1}{n} \sum_1^n d_{ki}$ ,  $k = 1, 2$ , can be

Card 2/3

Shape of the angular distribution ...

S/056/62/043/002/015/053  
B102/B104

obtained experimentally. Expectation value and standard deviation of these quantities are given by  $\nu(\bar{d}_k) = 0$  and  $\sigma(\bar{d}_k) = 1/\sqrt{n}$ , respectively. If one of the  $\bar{d}_k$  values is not within the range  $-2/\sqrt{n} \leftrightarrow +2/\sqrt{n}$ , the distribution of  $x$  will be abnormal, at least for a part of the shower. By applying the criterion to showers for primary-nucleon energies of  $\sim 10^{11}$  ev it is shown that the distribution with respect to  $x = \log \tan \theta$  is abnormal. It is in qualitative agreement with the two-center model of multiple production (A.A. Yemel'yanov, ZhETF, 42, 171, 1962). There are 2 figures and 1 table.

in the crystal plane, the dislocation density, and the minority carrier lifetime were also investigated. The values of the principal tangential stresses in the single crystal were investigated. A correlation is established between the values of the principal stresses in the crystal and the dislocation density or the minority carrier lifetime. The possibility of observing tirefriction corresponding to screw-type impurity macro-inhomogeneity is demonstrated.

TITLE: The nature of the interaction between fast nucleons and  
heavy nuclei

PERIODICAL: Akademiya nauk Uzbekskoy SSR. Izvestiya. Seriya fiziko-  
matematicheskikh nauk, no. 4, 1962, 47 - 51

TEXT: The authors studied experimentally the angular distribution  
(S-system) of secondary particles in showers produced by charged particles.  
They observed growth properties of the anisotropy of which are qualitatively  
inconsistent with theoretical representations of the interaction between  
a nucleon and the flight-path "tube" of nuclear matter. If, however, the  
model of peripheral interactions is applied to rearrangement collisions of  
fast nucleons with heavy nuclei the increase of anisotropy in the S-system  
can be explained as due to an increased number of nucleus-target nucleons  
participating in the collision, as well as to the formation of a great  
number of ionized particles and the appearance of humps in shower  
particles. There is 1 figure.

TITLE: Angular distributions of secondary particles in pN collisions at 24 BeV energy

SOURCE: Zh. eksper. i teor. fiz., v. 47, no. 1, 1964, 24-29

TOPIC TAGS: pion scattering, angular distribution, nucleon scattering, dispersion analysis, nuclear emulsion

ABSTRACT: The research was undertaken because asymmetric emission of particles was observed in nucleon-nucleon collisions at energies of several hundred BeV (V. V. Guseva et al., Izv. AN SSSR, Ser. fiz., v. 26, 549, 1962. N. A. Dobrotin et al., Nuclear physics v. 35, 152, 1962). The statistical method of dispersion analysis (the F test) is used to check the hypothesis of independent secondary-particle

1/3

ACCESSION NR: AP4042364

emission angles in inelastic pN interactions involving primary protons of equal energy E and equal numbers n of charged secondary particles. The experimental values of F for pN interactions at 24 BeV and for 4--9 charged secondary particles conflict with this hypothesis and indicate nonuniformity of the angular distributions in the laboratory system. This nonuniformity cannot be accounted for by momentum conservation in knock-on collisions and is associated with the particle production mechanism in peripheral interactions. The efficiency of the F-test for determining nonuniform angular distribution in the laboratory system was checked by investigating the random stars obtained from a somewhat different model of NN interactions at 300 BeV, by obtaining the spectrum of meson cloud velocities in the center of mass system and the secondary-particle energy spectrum in the rest system of the meson cloud. An accelerated on-track scanning of plates bombarded with 24-BeV protons in the CERN accelerator has shown that for the stars observed in the emulsion the most values of F exceed unity, meaning that the emission angles of the secondary particles are not independent at least for some

2/3

ACCESSION NR: AP4042364

values of n. The nonuniformity of the angular distributions is similar to the asymmetric c.m.s. particle emission observed in NN collisions at  $\sim 10^{11}$  eV. The peripheral interactions at E-24 BeV remains dominant up to a multiplicity n = 9. "The authors are grateful to W. O. Lock for collaborating in the acquisition of the photographic plates exposed in the CERN accelerator." Orig. art. has: 2 figures and 19 formulas.

no. 4, 1964, 1273-1278

TOPIC TAGS: cosmic ray shower, nuclear cascade, angular distribution, two center model

ABSTRACT: Inasmuch as the two-center model of multiple particle production cannot be regarded as definitely proved, the authors describe a new method for a quantitative testing of this model in the angular distribution of shower particles. To this end, methods are proposed for quantitative tests of various models of multiple production of particles in high energy NN collisions.

Card 1/3

L 13495-65

**ACCESSION NR:** AP4047895

sions. The method is based on the use of a uniform distribution for the secondary particles relative to a quantity  $y$ , defined by

$$y = \int_{-\infty}^x p(t | \gamma_1, \gamma_2, \alpha) dt,$$

regardless of the parameters  $\gamma_1$ ,  $\gamma_2$ , and  $\alpha$  ( $\gamma_1$ ,  $\gamma_2$  -- Lorentz factors in the laboratory frame of the fast and slow centers, respectively;  $\alpha = n_1 / (n_1 + n_2)$ , where  $n_1$  and  $n_2$  are the numbers of charged particles emitted by these centers). The distribution parameters are estimated by the method of moments. The angular distribution of the secondary shower particles produced in a photographic emulsion by nucleons with energies exceeding  $10^{12}$  eV is compared with the predictions of the usual two-center model and of the Hasegawa many-center model. It is concluded that the Hasegawa model does not agree with the experimental data. The authors thank E. G. Bubelev for a discussion of the work and for valuable remarks." Orig. art.

TITLE: Azimuthal angular distribution of shower particles and gray tracks produced by cosmic ray particles in emulsion

SC: S: Yadernaya fizika, v. 3, no. 1, 1966, 112-115

TOPIC TAGS: cosmic shower, cosmic ray particle, angular distribution, cosmic ray anisotropy, correlation function, PARTICLE TRACK

ABSTRACT: This is a continuation of earlier work by the authors group (ZhETF v. 45, 407, 1963) where a procedure was developed for observing different correlations in the azimuthal angular distribution. The present article is devoted to the azimuthal angular distribution of gray tracks of shower particles in stars produced in emulsion by singly charged particles, and satisfying the selection rules  $n_h + n_g > 15$ ,  $n_g \geq 10$  ( $n_h + n_g$  - number of strongly ionized particles,  $n_g$  - number of shower particles). A gray track is defined as one with a grain density larger than  $1.4g_0$  ( $g_0$  - grain density of fast-electron track) and a range larger than 2.5 mm, corresponding to a proton kinetic energy not lower than 25 Mev. The investigation covered 33 showers of ~50 Gev energy. The procedure involves introduction of specially defined random quantities, the mean values of which are determined separately for the shower.

Card 1/2

L 34475-66

ACC NR: AP6016812

4

particles and for the gray tracks. From the distribution of the showers relative to these random quantities, it is concluded that the shower particles as well as the gray tracks exhibit azimuthal asymmetry. Furthermore, there is a tendency for these two groups of particles to be emitted in opposite directions. The observed effects are qualitatively explained by using the concept of development of an intranuclear cascade. The authors thank I. M. Gramenitskiy for a discussion of the work, and Sh. Abduzhamilov, L. P. Chernova, and G. M. Chernov for measuring the shower-particle emission angles. Orig. art. has: 3 figures, 4 formulas, and 1 table.

TITLE: Coherent interaction of high-energy protons with complex nuclei

SOURCE: Yadernaya fizika, v. 3, no. 4, 1966, 657-662

TOPIC TAGS: proton, high energy proton, photoemulsion, nucleon, particle  
interaction, proton interaction, inelastic interaction

ABSTRACT: The authors use a method proposed in a previous work [Sh. Abduzhamilov, S. A. Azimov, L. P. Chernova, G. M. Chernov, V. M. Chudakov ZhETF, 47, 24, 1964] to find and analyze in detail the differences between the angular distributions of secondary particles in showers formed by high-energy protons and satisfying the necessary selection criteria for pp and pn collisions in

Card 1/2

L 45314-66

ACC NR: AP6023083

photoemulsions. These differences are easily explained by the inclusion of coherent interactions. The method of research is also explained in detail. Experimental data are presented and discussed. The results are discussed of processing the showers formed in photoemulsions by protons with 24 gev and satisfying the necessary criteria of selection of pn collisions. Measurements have been made previously by the authors, the number of particles being  $n \geq 4$ . The differences found indicate the possible existence of coherent interactions of protons with complex nuclei among the showers with three and four secondary charged particles at 10 and 24 gev. The authors also used measurements made at the Laboratory of High Energies of the Joint Nuclear Research Institute (OJYal) during investigation of inelastic pn interactions of protons with an energy of 10 gev with free and quasi-free nucleons of the photoemulsion. The authors are grateful to V. I. Veksler for permission to use the experimental data obtained at the LVE OJYal, and to M. I. Podgoretskiy for discussions of the work. Orig. art. has: 2 figures, 15 formulas, and 1 table.

"Inelastic  $\pi$ -p- Interactions with Slow Recoil Protons at 17 GeV"

Moscow, Yadernaya Fizika; July, 1966; pp. 169-177

27

B.

**ABSTRACT:**  $\pi$ -p- interactions with free and quasifree photoemulsion protons, in which 4 and 6 secondary charged particles are emitted, have been investigated. A method of analyzing the angular correlations and the distribution of residual effective masses is described which can prove useful in investigating multipion resonances. Experimental data indicate the possible existence of a resonance with the mass 3.2 GeV. The authors thank V. O. Lok for his kind assistance in the acquisition of photographic plates irradiated on the TsYeRN accelerator; M. I. Podgoretskiy for discussion of the work and valuable advice; and T. V. Zagudaylo, A. G. Imanbayev, and Ye. A. Til', who participated in the review of the calculations. Orig. art. has: 6 figures, 16 formulas, and 1 table. [Based on authors' Eng. abst.]

TOPIC TAGS: IR scanning, optic analysis, optic scanning, IR analysis, IR system, elasticity

ABSTRACT: Application of IR to optical-electronic measurement of elastic deformations in opaque (to the visible spectrum) materials is described. The method consists in scanning of the sample by a narrow beam of infrared radiation, registering the transmitted radiation with an IR detector, converting the resultant electrical currents after amplification into visible light of varying intensity in a lamp, and recording this visible light on photographic film. The intensity of recorded light depends on the transmittance and birefringence of a given sample. In this manner elastic changes due to pressure in normally opaque materials, such as semiconductors, plastics, cer-

Card 1/3

tain types of glass, etc., can be investigated and recorded. The basic equipment, a polariscope, is shown in Figure 1. The wavelength of the IR radiation can be selected for best transmission through the given material. For kinematic studies of material deformation due to stress as a result of heat, another instrument was devised and is shown in Figure 2. In this instrument the intensity of radiation transmitted

TOPIC TAGS: photoelectric method, stress, heterogeneity, semiconductor crystal, IR polariscopy, flaw detection

TRANSLATION: There is developed a method of photoelectric infrared polariscopy and flaw detection, consisting in consecutive measurement, at individual points of semiconductor crystals, of values of transmission and birefringence that characterize their structural imperfections. The method also makes it possible to visually observe the pictures of transmission and birefringence distribution obtained in the infrared region of the spectrum. The apparatus used in this method

Card 1/2

ACCESSION NR: AR4044002

operates on the principle of scanning using high-sensitivity infrared-radiation receivers. To obtain quantitative data, the electrical signal generated in the infrared receiver is amplified and recorded by a measuring device. The electrical signal can also be converted into visible light. When using a microscope with this method it is possible to study various structural flaws. There have been designed PIK-1 and infrared polarization scanning microscope to investigate structural flaws in silicon and germanium crystals.

TOPIC TAGS: IR polariscope, alloy junction, silicon crystal, crystal, birefringence

TRANSLATION: Studies high-resistance n-type silicon single crystals grown by the Czochralski method in a vacuum, and He with resistivity of 20-100 ohm-cm. Birefringence in crystals is studied by the method of photoelectric infrared polariscope. It is found that during crystal growth there arise stressed regions near the lateral face; the stresses reach up to 63 kg/cm<sup>2</sup>. For plates cut perpendicular to the axis of growth it is shown that stresses along the axis of the bar spread non-uniformly; maximum birefringence occurs at the ends of the bar. There were in-

Card 1/2

ACCESSION NR: AR4044004

vestigated plates cut at an angle to the growth axis. In this case, stresses in regions with maximum birefringence in these plates are considerably smaller in value and spread more uniformly.

ACCESSION NR: AR4046004

agree with the distributions in the dislocation density, determined from the etch figures. It is indicated that in technological investigations the method of birefringence study is less laborious than the method of dislocation study. V. Sintsov.

TITLE: Calculation of the elastic binding coefficients and compressibility of  
spins

TOPIC TAGS: Fizika tverdogo tela, v. 7, no. 7, 1965, 2254-2256

TOPIC TAGS: crystallography, spinel structure, spectrum analysis, elastic modulus  
ABSTRACT: Elastic constants and compressibilities of some ferrites were calculated  
from the frequency spectrum of a spinel-type linear series. The values of the frequencies were obtained by using data from the literature. An analysis of the experimental data showed that for isomorphic displacement of one of the cations, the low frequency band of the infrared spectrum changed slightly and this resulted in oscillations of the lighter oxygen atoms in the spinel lattice. Theoretical and experimental results for the frequencies of spinel-type linear series were calculated for  $\text{Fe}_3\text{O}_4$ ,  $\text{NiFe}_2\text{O}_4$ ,  $\text{CoFe}_2\text{O}_4$  and  $\text{ZnFe}_2\text{O}_4$ ; along with the maximum and minimum frequencies of the infrared spectrum, the compressibility,  $1/\beta$ , was calculated from the following formula:  
$$1 = 2C_{11} - 2C_{44}$$

TITLE: Determination of the energy spectrum of an impurity ion with an unfilled d-shell  
in a crystal

SOURCE: Optika i spektroskopiya, v. 19, no. 4, 1965, 586-596

TOPIC TAGS: crystal impurity, EPR spectrum, line splitting

ABSTRACT: The interpretation of energy spectra and EPR spectra of ions in various crystals requires the solution of a secular equation which takes into account the configuration of the ion and the symmetry of the intracrystalline field. In this paper, tables of matrix elements have been compiled which make it possible to write a secular equation at once for any term of any configuration in the case of an impurity ion with an unfilled d shell. These tables can also be used in studying EPR spectra if the field of lower symmetry produces a splitting comparable in order of magnitude to other perturbations (spin-orbital and exchange perturbations, etc.). As an example, the splitting of the principal

card 1/2

L 14624-66  
ACC NR: AP5025303

terms D and F in fields of variable symmetry was analyzed. Data on the optical spectra of Cr<sup>3+</sup> in MgAl<sub>2</sub>O<sub>4</sub> make it possible to determine local distortions caused by Cr<sup>3+</sup> ion which replaces Al<sup>3+</sup> ion at the octahedral sites of spinel. The data obtained are in good agreement with the experiment. Orig. art. has: 7 tables and 6 formulas.

TITLE: Using the method of infrared polariscopy for investigation of allcy-junction simulators, and the effect of machining on the birefringence of silicon crystals

CITED SOURCE: Sb. Metod fotoelektr. infrakrasn. polyariskopii i defekroskopii poluprovodnik. materialov. M., 1962, 16-21

TOPIC TAGS: pn junction, silicon crystal birefringence

TRANSLATION: Single n-Si crystals grown in vacuum and in He by the Chokhral'skiy method with a resistivity of 20--100 ohms-cm were studied. Simulators of p-n junctions were prepared by alloying Al-foil at 600C. The crystal birefringence was studied by the method of photoelectric IR-polariscope. It was found that, during the crystal growing, stressed regions near the side surface arise, the stresses reaching  $63 \text{ kg/cm}^2$ . In the plates cut along (111), i. e., at right angles to the growth axis, the stresses along the ingot axis are distributed irregularly; the highest birefringence occurs at the ingot ends. Also plates cut along the (100) plane,

L 00943-66

ACCESSION NR: AR5004725

i. e., at an angle to the growth axis were investigated. In this case, the stresses in the maximum-birefringence regions were much lower and distributed more uniformly than in the plates cut along (111). In the plates intended for devices the stresses were relieved in the process of cutting. In preparation of a p-n junction by the alloy method, a birefringence arises which corresponds to tangential stresses up to 70 kg/cm<sup>2</sup>. Bibliography: 4 titles.

TOPIC TAGS: semiconductor crystal, structural defect, crystal defect

TRANSLATION: A method was developed of photoelectric IR-polariscopy and flaw detection which involves successive measurement of transmission and birefringence at separate points of a semiconductor crystal; this characterizes the structural defects of the crystal. The method also permits visual observation of the pattern of distribution and birefringence in the IR spectral region. The equipment involved operates on the principle of scanning a beam and uses high-sensitivity IR receivers. In order to obtain quantitative data, the electric signal of the IR

Card/2

L C0939-66

ACCESSION NR: AR5004726

receiver is amplified and recorded by an instrument. This electric signal can also be converted into visible light. In conjunction with a microscope, the method permits studying structural defects. These instruments operating according to the above method have been designed and built: IR-polariscope PIK-1 and IR-polarization microscope with a scanning device intended for studying structural defects in Si and Ge crystals.

Chudakova, I.K., Volynskiy, N.P. Determination of Sulfur Content in Heavy  
Petroleum Products by Double Combustion 352

This is a new method proposed for the double combustion for the determination of sulfur in all types of petroleum products, with the exception of gasoline and low-sulfur kerosene, and in individual organic compounds containing C, H, O, N, and S. This method is more exact than the bomb and VTI methods. There are 6 tables, 5 figures, and 5 references of which are 4 Soviet and 1 English.

Author: Batalin, R.D. (Chairman) (1959, No. 22.) Doctor of Chemical Sciences; G.I. Gulyamova (V.P. Ponomarev, Candidate of Technical Sciences); Ya. S. Chernyayev, Doctor of Technical Sciences; V. V. Gulyamova, Candidate of Chemical Sciences; and V. P. Ponomarev, Candidate of Chemical Sciences; Ed. by Publishing House: I.L. Shchegoleva, Publ. No. 1, Leningrad, 1959. 576 p.

Review: This book is intended for chemists, chemical engineers, and technicians specialized in the chemistry of petroleum. It contains the results of a collection of papers presented at the First Scientific Session on the Chemistry of Organic Salts and Nitrogen Compounds contained in Petroleum and Petroleum Products. The collection consists of six sections: 1) Synthesis, 2) Separation, 3) Fractionation, 4) Analysis of organic sulfur compounds; 5) Preparation of organic sulfur compounds containing sulfur by thermal catalysis; 6) Preparation of organic sulfur compounds by sulfide-catalyzing petroleum products; 7) Use of organic sulfur compounds and hydrogen sulfide in the production of organic sulfur compounds; 8) Preparation of organic sulfur compounds; 9) Use of organic sulfur compounds and hydrogen sulfide in the production of organic sulfur compounds. In parentheses are mentioned: 200 references, 200 diagrams, and 1 chart.

TITLE: Results of deep seismic sounding<sup>1/2</sup> of the earth's crust in the central Urals  
SOURCE: AN SSSR. Izvestiya. Fizika Zemli, no. 4, 1966, 36-44  
TOPIC TAGS: deep seismic sounding, seismic profile, seismic discontinuity, deep drilling, Moho discontinuity  
ABSTRACT: In 1962—1964 the Bizhenovsk Geophysical Expedition of the Ural Geological Administration of the Main Geological Administration of the RSFSR and the Institute of Geophysics of the Ural Branch of the Academy of Sciences SSSR carried out deep seismic soundings (GSZ) along a 450-km, east—west profile across the Urals between Krasnoufimsk on the west and Tyumen on the east. Both the GSZ and KMPV (longitudinal wave correlation) methods were used. In the GSZ operations, six shot points, spaced about 100 km apart with travel times of 300 km, were supplemented in the Asbest region by quarry explosions detonated Card 1/2 2  
UDC: 550.834:550.311

L 22928-66

ACC NR: AP6013163

simultaneously with the GSZ shots. Three shot points, spaced about 25 km apart with travel times of 50 km, were used in the KMPV operations. Instruments used in the KMPV method were SS-30/60 stations with SPEN-1 seismographs; the filtration was 2-2 for distances of less than 100 km, and 1-1 for longer distances. Seismographs were arrayed in groups of 3-4, 10-20 m apart with 100 m between the groups. Six main groups of reflected and refracted waves were distinguished (three discontinuities in the upper crust and three in the lower crust), the surfaces of the granite-gneiss basement and the Moho discontinuity being the best defined. Analysis of the seismographic data showed that the crust and upper mantle is layered, that the crust is characterized by a fault-block structure, and that the Moho discontinuity is downwarped under the Urals. The authors evaluate the data obtained in this study as being of great value in selecting the site for deep drilling in the Urals and recommend that additional profiles be run, especially in the Tagil'-Magnitogorsk area where an explanation for the 7000 m/sec velocity discovered in the present study at a depth of 5-6 km might be obtained. Orig. art. has: 3 figures.

Use method for measuring resistance

1. Basic principles of measurement of semiconductor resistance

2. Application of the method to the measurement of the resistance of rectifying elements with different types of contacts

3. Controlled semiconductor rectifying elements and their applications

TOPIC TAGS: semiconductor, semiconductor resistance, semiconductor resistance measurement

ABSTRACT: The equipment involved, theory, and experimental results obtained with an impulse method of measuring the resistance of semiconductors are described. A pair of square impulses, one of each polarity, is amplified and applied to a cathode follower. The impulse repetition rate can be controlled; the impulse duration is  $1\mu$  sec. The method promises accurate measurement of the semiconductor resistance if the shunting capacitance of the wiring is held within

Card 1/2

L 5018-65

ACCESSION NR: AT5013582

certain limits (formula 7). The method also permits measuring (with an error of up to 25%) the resistance of a semiconductor when the latter presents a considerable capacitance. The method was also used for measuring small-size resistors (from 1 ohm to 100 ohms) with good results. Resistors with a resistance of 100 ohms and more (from 100 ohms to 10 kilohms) when the wiring capacitance was under 0.1 pF and 5 kilohms when the resistors could be reliably measured when the wiring capacitance was 0.1 pF. The method was verified by measurements made on germanium and silicon metal-alloy resistors. The statistical error was 10% for the first 10 figures and 20 formulas.

TITLE: The azimuthal angular distribution of shower particles

PERIODICAL: Zhurnal eksperimental'noy i teoreticheskoy fiziki, v. 40,  
no. 1, 1961, 156-162

TEXT: An experimental verification of the two-center model of multiple particle production in collisions of fast nucleons by means of the angular distribution (with respect to the angle between the orbits of primary and secondary particles) is unfavorable, because the effect is mostly of the same order as the natural statistical oscillations. To confirm the utility of this model, the finding of an anisotropy of the azimuthal angular distribution of secondary particles appears to be better suited (insofar as it is not surpassed by statistical fluctuations). Theoretically, the azimuthal asymmetry of the angular distribution of fast particles produced in collisions between nucleons and complex nuclei has already been studied by means of the Pearson criterion, but no existence of an azimuthal asymmetry could be proven. This is, however, ascribed to the fact that, in order to be able

The azimuthal angular distribution...

to apply this criterion, a large number of secondary particles must exist. For the case in which only a small quantity of secondary particles exists, the author in the present paper shows that it is also possible, and more favorable, to apply the  $\chi^2$ -criterion for the finding of an azimuthal asymmetry of secondary particles. Here, the lack of particles in individual showers may be compensated by a large quantity of showers. To study the angular distribution, the total azimuthal angle  $2\pi$  was decomposed into  $m$  equal integrals, and the number of particles ( $n_k$ ) in each integral was

calculated ( $\sum_{k=1}^m n_k = n_s$ , the total quantity of secondary particles). If azimuthal isotropy and statistical independence of the departure angle  $\psi_i$  of the secondary particles is assumed, one will find that in the case of large  $n_s$ , an  $\chi^2$ -distribution with  $m-1$  degrees of freedom exists. Here, the mathematical expectation and dispersion of these quantities for arbitrary  $n_s$  is calculated ( $\lambda_m^2 = \frac{m}{n_s} \sum_{k=1}^m n_k^2 - n_s$ ). For this purpose, the quantity  $d_m = \lambda_m^2 / (m-1)$  is introduced, and using the Chebyshev inequality and the

The azimuthal angular distribution...

theorem by Lyapunov, the following result is obtained: If azimuthal isotropy of the angular distribution of each particle with arbitrary  $\theta$  and fixed direction of the remaining  $n_s - 1$  particles is assumed, the mathematical expectation of the quantity  $\alpha$  and its dispersion is given by

$$\begin{aligned} M(\alpha) &= \int \alpha f(\theta_1, \varphi_1, \theta_2, \varphi_2, \dots, \theta_{n_s}, \varphi_{n_s}) \prod_{i=1}^{n_s} d\theta_i d\varphi_i = \\ &= \int \alpha f_1(\theta_1, \theta_2, \dots, \theta_{n_s}) \prod_{i=1}^{n_s} d\theta_i d\varphi_i / 2\pi = 1, \end{aligned} \quad (14)$$

$$\begin{aligned} D(\alpha) &= \left[ \left[ \sum_{i=1}^{n_s} \sin^2 \theta_i \right] / \left[ \sum_{i=1}^{n_s} \sin^2 \theta_i \right]^2 \right] f_1(\theta_1, \dots, \theta_{n_s}) \prod_{i=1}^{n_s} d\theta_i d\varphi_i / 2\pi = \\ &= M[1 - \overline{\sin^4 \theta} / n_s (\overline{\sin^2 \theta})^2] < 1. \end{aligned} \quad (15)$$

where  $f(\theta_1, \varphi_1, \theta_2, \varphi_2, \dots, \theta_{n_s}, \varphi_{n_s})$  is the probability density of multi-dimensional distribution. In the most general case,  $\alpha$  differs from unity by the following:  $M(\alpha) - 1 = aM[n_s(\overline{\sin^2 \theta})^2 / \overline{\sin^4 \theta} - 1] \geq 0$ ,  $a = [M(\cos \psi)]^2 + [M(\sin \psi)]^2$ .

B102/B204

The azimuthal angular distribution...

The method suggested here is now used for the purpose of analyzing the azimuthal angular distribution of secondary particles in "jets" produced in photographic emulsions by singly charged cosmic particles. The experimental data used were obtained at Ya. Pernegr's laboratory. The  $d$ -values for 52 showers with  $n_s$  between 6 and 42, and Lorentz factors (in the c.m.s.) between 2.4 and 150 were calculated. The results obtained indicate the existence of a symmetric but anisotropic azimuthal angular distribution in individual showers. The experimental data are in contradiction to the hydrodynamic theory of "jet" formation in central collisions in the case of a cylindrical symmetry of secondary particles, and indicate an important part played by peripheral collisions. Meson emission occurred mainly near the plane, which is perpendicular to the direction of the spin of the excited center which appears theoretically to be a consequence of the two-center model of the multiple production in high-energy nucleon-nucleon collisions. The author thanks S. A. Azimov, M. I. Podgoretskiy and D. S. Chernavskiy for remarks, Ya. Pernegr for the experimental data, and G. M. Chernov for his assistance. There are 1 table and 10 references.
